n non-equilibrium systems, transport is a widely studied phenomenon. In a macroscopic world, a ball rolls down an inclined plane due to potential difference, heat flow occurs from hotter end of a rod to colder end of the rod due to thermal gradient, osmosis is known to occur due to concentration gradient, electric current flows due to potential difference. In these examples, forces in the form of gradients are involved to generate directed flow or motion in the system. Hence, force-free or gradient-free systems are known not to lead to directed motion at macroscopic scales. At microscales, thermal fluctuations become dominant, therefore it requires incessant input of energy to maintain gradients at such scales. The order of input energy to perform work is continually washed out by thermal fluctuations. Hence transport mechanism becomes complex. But, surprisingly, protein

motors in our body can transport cargo or energy packets across microtubules in the face of inescapable thermal noise. What happens to

"In noisy systems, fluctuations can be rectified to obtain directed motion with zero average force using ratchet mechanism"

transport at microscales? Can the same idea of transport via gradients be implemented at a microscale? Will transport be efficient? In this article, we talk about the transport mechanisms at scales as small as a living cell. Inspired by the fascinating mechanism by which protein motors move in the face of thermal noise, many physicists are working to understand these molecular motors . Among the various models proposed to explain the working of molecular motors the Brownian motor is one such model [1]. A Brownian motor combines Brownian motion with an external asymmetric profile called ratchet to help achieve directed motion. But asymmetry alone cannot lead to directed motion until unless time-reversal symmetry is broken. In literature, asymmetric periodic forces in combination with Brownian motion are considered as an archetype for bio-engines that work on chemical synthesis and conformational changes [2].

## Is Directed Motion Possible in a Noisy System With Zero Average Force?

Anshika Chugh (PhD Student, Plasma Devices Theory and Simulation Division, IPR) Email: anshika.chugh@ipr.res.in

<sup>(</sup>b) Ratchet profile over one spatial period is shown in blue.  $U_R(x) = -(\sin(2\pi x/L) + 0.25 \sin(4\pi x/L))$ . In normalised units  $\Delta U = 1$ 

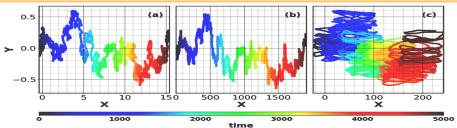

Figure 2: Time evolution of average position of system of interacting particles for three different values of amplitudes of driving strengths  $A_d$  at driving frequency  $\omega$  = 0.2, (a) For  $A_d$  = 0.50 average distance travelled in x-direction is 15L in 5000  $au_0$ , (b) For  $A_d$  = 1.60 average distance travelled in x-direction is 1900L in 5000  $au_0$  , (c) For A<sub>d</sub> = 4.50 average distance travelled in xdirection is 330L in 5000  $\tau_0$ .

We have performed 2D Langevin simulations on Yukawa particles to demonstrate the emergence of directed motion in a system dominated by fluctuations [3]. We have used an in-house developed parallelized version of MPMD (Multi-Potential Molecular Dynamics) code. The code

> was modified to include ratchet profile, time-periodic drive, and related diagnostics to perform measurements on the system. Figure 1 shows the ratchet profile used in this study. The simu-

lation is carried out with 1024 particles in a 32 x 27.71 box with periodic boundary conditions along with both directions on ANTYA HPC Cluster. We used the Leapfrog integration scheme with step size 0.001 for the time integrating the equation of motion for each particle.

Yukawa system act as an interesting 'test bed' for investigating ratchet dynamics owing to its ease in tuning the interaction radius via screening length and its experimental viability through dusty plasma experiments. We use a timeperiodic drive to take the system out of equilibrium which in combination with thermal fluctuations help break time-reversal symmetry. The beauty of this study is that directed motion can be achieved even if all the external forces involved has zero spatial-temporal average. Fig. 2 shows the time evolution of the average position of the system defined through average over a number of interacting particles for three different values of the amplitude of driving Ad at driving frequency  $\omega = 0.2$ . One advantage of performing molecular dynamics simulation is that information about particles' positions and velocities can be known from the first principles and dynamics of the system can be extracted at both local and global scales. However, this information comes at the price of storing a large amount of data. In Figure 2, local information of the particles' average position can be seen in the form of oscillations which are large for the large amplitude of the periodic drive, while on a global time scale i.e. throughout total simulation time, forward motion is observed. The simulation data has been obtained using 32 cores with a run time of 13 hours. The above plot has been generated using 500000 data points amounting to 17 Mb of data.

We conclude that it is possible to achieve directed motion in the absence of any net force in the system with the help of a ratchet mechanism. This detailed published results are available in [3].

## Running MATLAB Programs on ANTYA Part-3: Access/Run MATLAB via Your Local Web Browser

For users not so much familiar with the Linux terminal command line and feel there are just too many things to learn before doing anything with MATLAB on ANTYA HPC cluster, then this part-3 of the MATLAB article shows the simplest way to use MATLAB through a web interface. MATLAB users need to have an HPC account in ANTYA and the same details are required on the login page of the web interface (Altair Access). This part-3 of the MATLAB series will demonstrate through snapshots how MATLAB can be accessed on ANTYA through a web interface. First open the URL in your local browser, provide your login credentials. To open a MATLAB session, click on "Sessions" Tab and then click on "Matlab". This will submit a job on the visualization node of ANTYA.

### ANTYA UPDATES AND NEWS

## 1. New Packages/Applications Installed

⇒ Upgraded NAG Compiler and NAG Library

The latest available versions are available with **modules:** NAG/nag-compiler\_71 NAG/nag-intel32-library\_27

#### DMTCP (Distributed Multi-Threaded Checkpointing) Tool

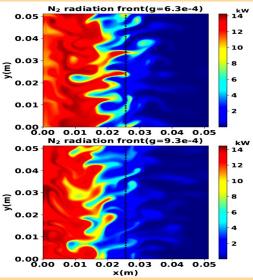

This is a checkpoint/restart tool for applications. The tool is available as module with name **dmtcp**.

#### OpenFOAM new module

OpenFoam 'plus' version, exclusively made for developers available as module with name **OpenFOAM-plus** 

#### HPC PICTURE OF THE MONTH

#### Effect of Turbulence on Impurity Transport in Boundary Region of a Tokamak

#### Pic Credit: Shrish Raj

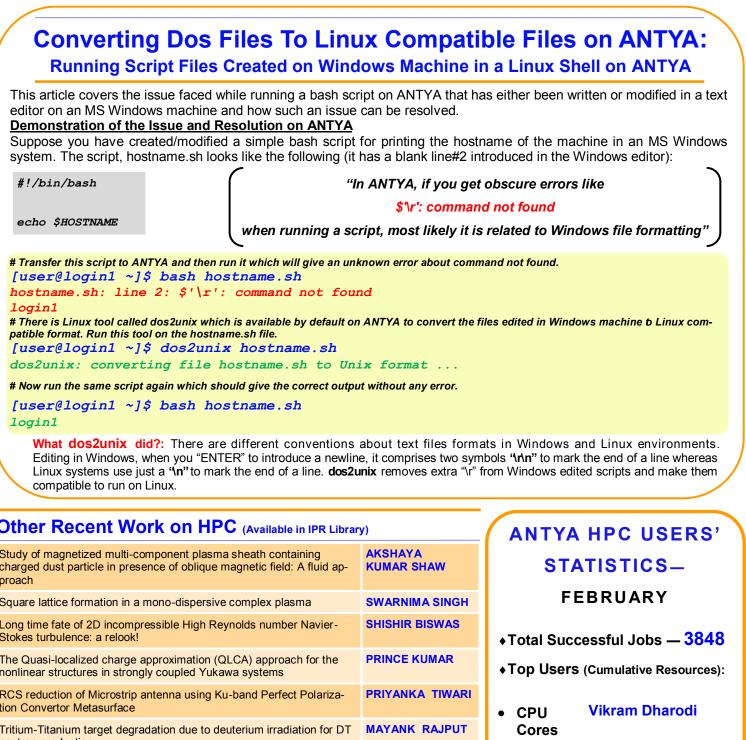

The figure shows an induced inward shift of the radiation cooling front with an increase in magnetic curvature induced effective gravity obtained with non-linear 2D BOUT++ simulation of plasmaimpurity interaction in the tokamak boundary for nitrogen gas seeding conditions. The vertical dotted line indicates the edge-to-SOL transition.

Data is obtained from BOUT++ code simulations on ANTYA and plotted with Python scripts.

## TIP OF THE MONTH

Did you know that PGI Compilers suite was rebranded and packaged as part of the NVIDIA HPC SDK (See <u>issue12</u>, page#3)?

pgcc => nvc pgc++ => nvc++ pgfortran and pgf90 => nvfortran

- GPU Cards
  - **Shishir Biswas** Walltime
    - Shrish Raj Jobs
